This pet has symblepharon, which is a fusion of conjunctiva (pink tissue around the eye) to each other or to the cornea. It occurs most commonly secondary to a previous severe infection of or trauma to the eye. These attachments can be surgically cut to allow for better vision and movement of the eye, but unfortunately they are likely to recur. Although they can affect vision by covering the cornea, these attachments are non-painful. All follow-up care will need to be done at the owner’s veterinarian and at the owner’s expense.
