This pet has been diagnosed with an upper respiratory infection. Upper respiratory infections can cause sneezing, discharge from the eyes and nose, and in severe cases lethargy and poor appetite. There are multiple causes of upper respiratory infections including a variety of viruses or bacteria. Some may be treated with antibiotics and others may resolve with time on their own, depending on the severity of the clinical signs. This pet may have been started on oral antibiotics if it was determined to be necessary. It is recommended to isolate this pet from other cats in the household until the pet’s clinical signs are completely resolved as the infection may be contagious to other cats. If the pet’s signs are worsening or not completely resolved by the time the course of antibiotics is completed, then a recheck with the owner’s veterinarian is recommended. Some cats may be infected with a virus that makes them prone to getting recurrent upper respiratory infections. If this is the case, stressful events such as moving to a new home may cause them to become sick. Any future diagnostics and treatments are to be done at the owner’s veterinarian and at the owner’s expense.
